## Exercise 1.

### 1.1 Haar Measure

Reminder:

- The moment operator is defined as  $\mathcal{M}^{(k)}(\cdot) := \mathbb{E}_{U \sim \mu_H}[U^{\otimes k}(\cdot)U^{\dagger \otimes k}]$  where  $\mu_H$  is the Haar measure.
- The commutant

$$\text{Comm}(U(d), k) := \{A \in \mathcal{L}((\mathbb{C}^d)^{\otimes k}) : [A, U^{\otimes k}] = 0 \forall U \in U(d)\}$$

is the set of linear operators  $A$  that commute with all  $U^{\otimes k}$ . Also, it holds that

**Exercise 1** (1 points; Haar). Show that  $\mathcal{M}^{(k)} \in \text{Comm}(U(d), k)$  and that if  $A \in \text{Comm}(U(d), k)$ , then  $\mathcal{M}^{(k)}(A) = A$ .

$$\begin{aligned} \mathcal{M}_k(A) &\in \text{Comm}(\mathcal{U}(d), k) \\ \Leftrightarrow V^{\otimes k} \mathcal{M}_k(A) V^{\dagger \otimes k} &= \mathcal{M}_k(A) \quad \forall V \in \mathcal{U}(d) \\ \Leftrightarrow V^{\otimes k} \mathcal{M}_k(A) &= \mathcal{M}_k(A) V^{\otimes k} \quad \forall V \in \mathcal{U}(d) \end{aligned}$$

$$\begin{aligned} \text{NB: } V^{\otimes k} \mathcal{M}_k(A) &= \mathbb{E}_U V^{\otimes k} U^{\otimes k} A U^{\dagger \otimes k} V^{\otimes k} \\ &= \mathbb{E}_U V^{\otimes k} V^{\dagger \otimes k} U^{\otimes k} A U^{\dagger \otimes k} V^{\otimes k} \\ (\text{using left invariance of the Haar measure}) &= \mathbb{E}_U U^{\otimes k} A U^{\dagger \otimes k} V^{\otimes k} \\ \mathbb{E}_U f(U) &= \mathbb{E}_V f(V^{\dagger} U) \\ &= \mathcal{M}_k(A) V^{\otimes k} \end{aligned}$$

$$\begin{aligned} \text{If } A \in \text{Comm}(\mathcal{U}(d), k) \text{ then } \\ \mathcal{M}_k(A) &= A \\ \text{This is because } \forall U, \quad U^{\otimes k} U^{\dagger \otimes k} &= A, \quad [A, U] = 0 \\ \Rightarrow \mathbb{E}_U U^{\otimes k} U^{\dagger \otimes k} &= A \\ &= \mathcal{M}_k(A) \end{aligned}$$

## Question 2

Reminder:

- $P_{\text{sym}} := \frac{1}{k!} \sum_{\pi \in S_k} V_d(\pi)$  where  $S_k$  is the symmetric group (group of permutations over  $k$  indices), and  $V_d(\pi) = \sum_{i_1, \dots, i_k \in [d]} |i_{\pi^{-1}(1)} \dots i_{\pi^{-1}(k)}\rangle \langle i_1 \dots i_k|$  affects this permutation on  $k$  many  $d$ -dimensional quantum systems.
- Schur-Weyl duality says that  $\mathcal{M}^k(O) = \mathbb{E}_{U \sim \mu_H}[U^{\otimes k} O U^{\dagger \otimes k}]$  can be expressed as a linear combination of  $V_d(\pi)$ , where  $O$  is a linear operator on  $(\mathbb{C}^d)^{\otimes k}$ .

**Question 2** (3 points). Prove that

$$\mathcal{M}^k(|\phi\rangle\langle\phi|^{\otimes k}) = \mathbb{E}_{U \sim \mu_H}[U^{\otimes k} |\phi\rangle\langle\phi|^{\otimes k} U^{\dagger \otimes k}] = \frac{P_{\text{sym}}}{\text{tr}(P_{\text{sym}})}$$

where  $|\phi\rangle \in \mathbb{C}^d$ . You could either do this directly yourself, or do it by establishing the following sub-steps.

- Show that  $V_d(\sigma^{-1})\mathcal{M}(\phi) = \mathcal{M}(\phi)$  where we use  $\mathcal{M}$  to denote  $\mathcal{M}^k$  and  $\phi$  to denote  $|\phi\rangle\langle\phi|$ .
- Show that  $\sum_{\pi \in S_k} c_\pi V_d(\sigma^{-1})V_d(\pi) = \sum_{\pi \in S_k} c_{\sigma\pi} V_d(\pi)$ .
- Can you use these two observations to conclude that  $\mathcal{M}(\phi) = \sum_{k \in S_k} c_{\sigma\pi} V_d(\pi)$ .
- Using your result above, reason that  $c_\sigma = c_I$  for all  $\sigma \in \pi$  (here  $I$  is the identity permutation)?
- Now, show that  $\mathcal{M}^k(\phi) \propto P_{\text{sym}}$
- Finally, establish the normalisation to complete the proof.

Theorem 22. Let  $d, k \in \mathbb{N}$ .

For all  $|0\rangle \in \mathbb{C}^d$ ,

the moment operator is a uniform linear combination of permutations, i.e.

$$\mathbb{E}_{U \sim \mathcal{N}_H} [U^{\otimes k} |0\rangle \langle 0| U^{\otimes k}] = \frac{P_{\text{sym}}^{(d,k)}}{\text{tr}(P_{\text{sym}}^{(d,k)})}$$

$\therefore P_{\text{sym}}^{(d,k)} = \frac{1}{k!} \sum_{\pi \in S_k} V_d(\pi)^k$

$\text{tr}(P_{\text{sym}}^{(d,k)}) = \dim(S_{\text{sym}}(C^d)) = \binom{k+d-1}{k}$

again it lacks it  
should be  $\binom{k+d-1}{d-1}$

Proof: Recall:  $\mathcal{M}_{\mu_H}^{(k)}(0) = \mathbb{E}_{U \sim \mathcal{N}_H} [U^{\otimes k} |0\rangle \langle 0| U^{\otimes k}]$

$$= \sum_{\pi \in S_k} c_\pi(0) V_d(\pi)$$

Strategy: left multiply both sides by  $V_d(\sigma^{-1})$  if  
using  $\ell$ /y..

NB1:  $V_d(\sigma^{-1}) \mathcal{M}_{\mu_H}^{(k)}((|0\rangle\langle 0|)^{\otimes k}) = \mathcal{M}_{\mu_H}^{(k)}((|0\rangle\langle 0|)^{\otimes k})$

- (i)  $V_d(\sigma^{-1})$  commutes w/  $|0\rangle\langle 0|$  &  $U$
- (ii)  $V_d(\sigma^{-1}) |0\rangle\langle 0| = |0\rangle\langle 0|$

NB2:  $\sum_{\pi \in S_k} c_\pi V_d(\sigma^{-1}) V_d(\pi)$

$$= \sum_{\pi \in S_k} c_\pi V_d(\sigma^{-1}\pi) = \sum_{\pi \in S_k} c_{\sigma\pi} V_d(\pi)$$

NB3: Combining [Recall], [NB1] & [NB2], we have

$$\mathcal{M}_{\mu_H}^{(k)}((|0\rangle\langle 0|)^{\otimes k}) = \sum_{\pi \in S_k} c_{\sigma\pi} V_d(\pi)$$

NB4: For  $d > 1$ ,

$$[NB3] \Rightarrow c_\sigma = c_I \quad \forall \sigma \in S_k$$

(take  $\sigma$  to permute any two indices &  
take the difference;

linear independence of  $\{V_d(\pi)\}_{\pi}$  is not  
needed - just that they are distinct  
operators).

NB5: Thus,  $\mathcal{M}_{\mu_H}^{(k)}((|0\rangle\langle 0|)^{\otimes k}) = c_I \left( \sum_{\pi \in S_k} V_d(\pi) \right)$

$$C_I \leftarrow k! P_{Sym}^{(d,k)}$$

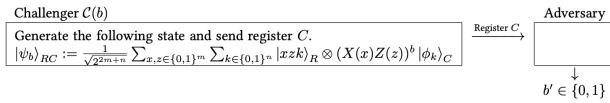

The constants can be fixed by noting the type of the RHS.

□

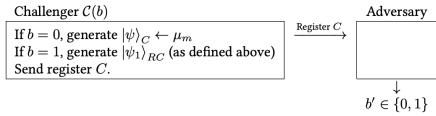

## Exercise 2

Reminder: Recall that for proving computational hiding of their commitment scheme, [4] consider the following hybrids. Below,  $|\phi_k\rangle$  is an  $m$ -qubit state produced by the state generator function of PRSG (with security parameter  $\lambda$ ) and  $\mu_m$  is the Haar measure over  $m$ -qubit states.

- $\text{Hyb}_0(b)$

- $\text{Hyb}_1(b)$

**Exercise 2** (1 point; PRSG  $\implies$  Commitments). Show that  $|\Pr[1 \leftarrow \text{Hyb}_0(b)] - \Pr[1 \leftarrow \text{Hyb}_1(b)]| \leq \text{negl}$  for  $b = 1$  (note,  $b = 0$  is not asked, only  $b = 1$ ).

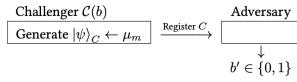

The two cases are in fact identical.

## Question 3

### 4 PRS $\implies$ Commitments

Reminder (PRSG  $\implies$  Commitments). In addition to  $\text{Hyb}_0, \text{Hyb}_1$  as defined above 2, [4] also define  $\text{Hyb}_2$  as follows.

- $\text{Hyb}_2(b)$

**Question 3** (2 points). We want to establish computational hiding of [4]'s commitment scheme by showing

$$|\Pr[1 \leftarrow \text{Hyb}_0(0)] - \Pr[1 \leftarrow \text{Hyb}_0(1)]| \leq \text{negl}(\lambda). \quad (2)$$

To this end, prove the following sub-claims (where we use  $a \approx b$  to denote  $|a - b| \leq \text{negl}$ ).

1.  $\Pr[1 \leftarrow \text{Hyb}_0(b)] \approx \Pr[1 \leftarrow \text{Hyb}_1(b)]$  for  $b = 0$  as well. Show that if this were not the case, then one can construct an adversary  $\mathcal{A}'$  that breaks the security of the underlying PRSG (pseudorandom state generator) by distinguishing a pseudorandom state from a Haar random state.
2.  $\Pr[1 \leftarrow \text{Hyb}_1(b)] \approx \Pr[1 \leftarrow \text{Hyb}_2(b)]$  for  $b = 0$  should be immediate (write one line justifying it). How will you modify  $\mathcal{A}'$  above to establish the  $b = 1$  case? Using these observations, establish (2).

Lemma 3.1:  $|\Pr[\text{Hyb}_0(b)=1] - \Pr[\text{Hyb}_1(b)=1]| \leq \text{negl}(\lambda)$

for each  $b \in \{0,1\}$ .

Proof of Lemma 3.1

N.B. clearly,  $\Pr[\text{Hyb}_0(0)=1] = \Pr[\text{Hyb}_1(0)=1]$

So we show  $|\Pr[\text{Hyb}_0(0)=1] - \Pr[\text{Hyb}_1(0)=1]| \leq \text{negl}(\lambda)$ .

Hence  $|\Pr[\text{Hyb}_0(0)=1] - \Pr[\text{Hyb}_1(0)=1]| \geq \text{non-negl}(\lambda)$ .

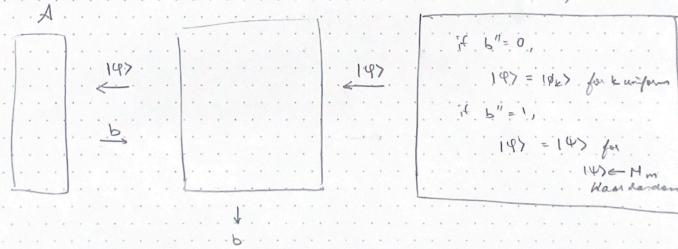

(for contradiction).

Story: Then one can construct an adversary  $A'$  that breaks the security of the PRSG.

Construction of  $A'$ :

$A'$

Challenger for  
the PRSG  
 $e'(b'')$

NB: When  $b'' = 0$ ,  $A$  sees  $\text{Hy}_{b_0}(0)$ .

When  $b'' = 1$ ,  $A$  sees  $\text{Hy}_{b_1}(0)$ .

thus,  $A'$  breaks the security of the PRSG.

□

For the second part, it suffices to show that the reduction  $A'$  behaves only slightly differently, i.e. sends  $X^X Z^Z |\psi\rangle$  instead of sending  $|\psi\rangle$

Lemma 3.2

$$|P_{\lambda}[\text{Hy}_{b_1}(b)=1] - P_{\lambda}[\text{Hy}_{b_2}(b)=1]| \leq \text{negl}(\lambda)$$

$$\forall b \in \{0,1\}$$

Proof of Lemma 3.2

NB:  $P_{\lambda}[\text{Hy}_{b_1}(0)=1] = P_{\lambda}[\text{Hy}_{b_2}(0)=1]$  is clear.

Story: We show that

$$|P_{\lambda}[\text{Hy}_{b_1}(1)=1] - P_{\lambda}[\text{Hy}_{b_2}(1)=1]| \leq \text{negl}(\lambda)$$

Suppose:  $|P_{\lambda}[\text{Hy}_{b_1}(1)=1] - P_{\lambda}[\text{Hy}_{b_2}(1)=1]| > \text{non-negl}(\lambda)$ .

(for contradiction)

Story: We can then construct an adversary  $A'$  that breaks the security of a PRSG.

$A$

$A'$

$e'(b'')$

if  $b'' = 0$   
 $14> = 14>$  for uniform  
if  $b'' = 1$   
 $14> = 14>$  for  $14> \in \mu_m$   
Hear random

□

NB: When  $b'' = 0$ , simulates  $\text{Hy}_{b_1}(1)$ .  
When  $b'' = 1$ , simulates  $\text{Hy}_{b_2}(1)$ .  $\therefore$  breaks security of -14-

## Exercise 4

### 1.4 QFHE

Reminder:

- Recall that Mahadev's QFHE scheme encrypts a quantum state  $|\psi\rangle$  as  $(X^x Z^z |\psi\rangle, (\hat{x}, \hat{z}))$  where  $x, z$  are sampled uniformly and  $\hat{x}$  and  $\hat{z}$  denote classical FHE encryptions of  $x$  and  $z$  respectively.

**Exercise 4** (1 point; QFHE). Explain how the Eval function is implemented for Clifford gates, in Mahadev's construction.

Reminder:  
- Suppose  $C$  is a Clifford gate.  
(Instead of a circuit).  
- It holds that  $\forall P_1, P_2$  in the Pauli grp.  
 $P_3 P_C$  in the Pauli grp s.t.  
 $C(P_1 \otimes P_2) C^\dagger = P_3 \otimes P_4$ ,  
 $\Rightarrow \exists x, z, \exists x' z' \text{ s.t. } C Z^x X^z |1\rangle = Z^{x'} X^{x'} |1\rangle$ .  
L  
- Therefore for all Clifford gates,  
Eval<sub>C</sub> simply applies this gate &  
updates the classical encryptions  
of  $z \times$  to  $z' \times'$ .  
(NB:  $z'$  &  $x'$  can depend on  $z, x$  &  
the gate).

## Question 6

### 5.2 QFHE

Reminder: We look at some of the steps that go into applying the encrypted CNOT operation in Mahadev's QFHE scheme. The question will ask you to fill in a detail or two. Let  $|\psi\rangle = \sum_{a,b \in \{0,1\}} \alpha_{ab} |ab\rangle$  be an arbitrary pure two qubit state. The goal is to apply  $\text{CNOT}^s$  where  $s$  is given (recall  $\hat{s}$  is a classical FHE encryption of  $s$ ).

[BEGIN SNIPPET]

1. Classically, compute a description of the claw-free pair  $(f_0, f_1)$  corresponding to  $\hat{s}$  (a reminder about the claw-free pair is appended, just in case).

2. Prepare the state

$$|\psi_1\rangle = \sum_{\substack{a,b,\mu \in \{0,1\} \\ r \in \mathcal{R}}} \alpha_{ab} |ab\rangle |\mu r\rangle |f_a(\mu, r)\rangle$$

and measure the last register to obtain a  $y$ . Denote by  $|\psi_{1'}\rangle$  the resulting state.

3. XOR  $\mu_a$  into the second register. This should result in

$$|\psi_2\rangle := \sum_{ab \in \{0,1\}} \alpha_{ab} (\mathbb{I} \otimes X^{\mu_0}) \text{CNOT}_{12}^s |a, b\rangle |\mu_a r_a\rangle$$

where  $f_0(\mu_0, r_0) = f_1(\mu_1, r_1) = y$ .

4. The last register is measured in Hadamard basis...

[END SNIPPET]

**Question 6** (1 point; QFHE). Write down  $|\psi_{1'}\rangle$  and prove that following step 3, one indeed gets the state  $|\psi_3\rangle$  (up to a change in variable names, depending on the choice you make in specifying  $|\psi_1\rangle$ ).  
(Hint: it may help to observe that  $|b \oplus \mu_a\rangle = X^{\mu_0} |b + a \cdot s\rangle$ ; if you use this, prove that it is true first)

Reminder: Additional properties we need from (N)TCFs (Noisy Trapdoor Claw-free Functions), given encryption  $\hat{s}$  of a bit  $s$ .

1. One can efficiently compute trapdoor claw-free functions  $f_0, f_1 : \{0,1\} \times \mathcal{R} \rightarrow \mathcal{Y}$  s.t.  $\forall (\mu_0, r_0), (\mu_1, r_1) \in \{0,1\} \times \mathcal{R}$  which is a claw (i.e.  $f_0(\mu_0, r_0) = f_1(\mu_1, r_1)$ ), it holds that  $\mu_0 \oplus \mu_1 = s$ .
2. One can also compute a classical FHE encryption of the trapdoor (which allows one to invert the function) corresponding to the pair  $(f_0, f_1)$ .

$|\psi_1'\rangle$  should look something like this

Let  $(\mu_0, r_0), (\mu_1, r_1)$  be the two pre-images of  $y$ ,  
i.e.  $f_0(\mu_0, r_0) = f_1(\mu_1, r_1) = y$ .

Then, the remaining state is

$$\sum_{a,b \in \{0,1\}} \alpha_{ab} |ab\rangle |\text{H}_a \text{S}_b\rangle$$

and  $|\psi_3\rangle$  should be justified along the following lines

3.  $\text{XOR } \mu_a$  into the second register, i.e.

$$\sum_{a,b \in \{0,1\}} \alpha_{ab} |a,b \oplus \mu_a\rangle |\text{H}_a \text{S}_b\rangle =$$

$$(\because \mu_a \oplus \mu_b = s) \quad \sum_{a,b \in \{0,1\}} \alpha_{ab} (I \otimes X^{\mu_b}) |a, b + a \cdot s\rangle |\text{H}_a \text{S}_b\rangle =$$

$$(\text{by applying } \text{CNOT}_{12}^s) \quad \sum_{a,b \in \{0,1\}} \alpha_{ab} (I \otimes X^{\mu_b}) (\text{CNOT}_{12}^s |a,b\rangle |\text{H}_a \text{S}_b\rangle)$$

## Exercise 5

Reminder: In class, we only considered self-testing of the two-qubit maximally entangled state  $|\phi^+\rangle := \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$ . We considered the CHSH game where Alice and Bob are asked questions  $x, y \in \{0,1\}$  and respond with answers  $a, b \in \{\pm 1\}$  respectively. To describe the most general quantum strategy, denote the quantum state shared by Alice and Bob by  $|\psi\rangle_{AB}^{AB}$  where Alice holds register  $A$  and Bob register  $B$ . Denote the observable used by Alice (resp. Bob) to answer question  $x$ , by  $A_x$  (resp.  $B_y$ ). We observed that  $A_x$  and  $B_y$  are Hermitian and unitary.

**Exercise 5** (1 point; Self-testing). Suppose  $\frac{A_0 + A_1}{\sqrt{2}} |\psi\rangle = B_{0/1} |\psi\rangle$  where  $\{A_x\}_{x \in \{0,1\}}$  and  $\{B_y\}_{y \in \{0,1\}}$  denote Alice's and Bob's operators in a general strategy they follow to play the CHSH game. Prove that  $B_0$  and  $B_1$  anti-commute on  $|\psi\rangle$ , i.e.  $\{B_0, B_1\} |\psi\rangle = 0$ .

$$\frac{A_0 + A_1}{\sqrt{2}} |\psi\rangle = B_{0/1} |\psi\rangle, \quad (3)$$

$$\Rightarrow \{B_0, B_1\} |\psi\rangle = 0$$

$$\begin{aligned} \{B_0, B_1\} |\psi\rangle &= (B_0 B_1 + B_1 B_0) |\psi\rangle \quad (2*) \\ &= (A_0 - A_1) B_0 + (A_0 + A_1) B_1 |\psi\rangle \\ &= (A_0 - A_1)(A_0 + A_1) + (A_0 + A_1)(A_0 - A_1) |\psi\rangle \\ &= 0 \end{aligned}$$

## Question 5

### 5.1 Self-testing

Reminder: Continuing with the discussion preceding Exercise 5, recall that we explicitly defined the local isometry  $\Phi$  as shown in Figure 1. For  $Z_A = \frac{1}{\sqrt{2}}(A_0 + A_1)$ ,  $Z_B = B_0$ ,  $X_A = \frac{1}{\sqrt{2}}(A_0 - A_1)$ ,  $X_B = B_1$ , we proved in class that

$$\Phi[|\psi\rangle] = \sum_{i,j \in \{0,1\}} |ij\rangle_{A'B'} \otimes \underbrace{\left( \frac{1}{4} X_A^i (\mathbb{I} + (-1)^i Z_A) X_B^j (\mathbb{I} - (-1)^j Z_B) \right)}_{=: f_{ij}} |\psi\rangle_{AB}.$$

It may help to also recall that we proved the following:

- $\{Z_A, X_A\} = 0$ ,  $\{Z_B, X_B\} |\psi\rangle = 0$
- $Z_A |\psi\rangle = Z_B |\psi\rangle$  and  $X_A |\psi\rangle = X_B |\psi\rangle$

**Question 5** (1 point; self-testing). Using the aforementioned, show that that  $\hat{f}_{01}|\psi\rangle = \hat{f}_{10}|\psi\rangle = 0$  and  $\hat{f}_{11}|\psi\rangle = \hat{f}_{00}|\psi\rangle$ .

N.B.3: Using (35) — recall:  $z_A|\psi\rangle = z_B|\psi\rangle$ ,  
 $x_A|\psi\rangle = x_B|\psi\rangle$ ,

it holds that expression of the form

$$(1 \pm z_A)(1 \mp z_B)|\psi\rangle = 0$$

$$\Gamma: 1 \mp z_B \neq z_A + \underline{z_A z_B}$$

$$z_A^2 = z_A \quad \text{so} \quad z_A|\psi\rangle = z_B|\psi\rangle$$

$$|\psi\rangle = z_A z_B |\psi\rangle$$

$$\hat{f}_{01}|\psi\rangle = \hat{f}_{10}|\psi\rangle = 0$$

N.B.4:  $\hat{f}_{11}|\psi\rangle$  can be simplified as follows:

$$\hat{f}_{11}|\psi\rangle = \frac{1}{4} x_A (1 - z_A) x_B (1 - z_B)|\psi\rangle$$

$$(\text{using anti-commutator}) = \frac{1}{4} (1 + z_A) x_A (1 + z_B) x_B |\psi\rangle$$

$$\begin{aligned} (\text{from (35) \&} \\ \text{unitarity of } x_B) &= \frac{1}{4} (1 + z_A) (1 + z_B) |\psi\rangle \\ &= \hat{f}_{00}|\psi\rangle. \end{aligned}$$

### Exercise 3

#### 1.3 BQP=QMA yet PRUs exist

Reminder:

- Semi-formally, a pseudorandom unitary is a keyed family of unitaries  $\{U_k\}_{k \in \{0,1\}^\kappa}$  acting on  $n(\kappa)$ -qubits, where  $\kappa$  is a security parameter with the following two properties:
  - It can be applied efficiently (i.e. given  $k$  and a quantum state  $|\psi\rangle$ , one can efficiently compute  $U_k|\psi\rangle$ ) and
  - No efficient quantum algorithm  $\mathcal{A}$  can distinguish whether it is given oracle access to a Haar random unitary, i.e.  $U \leftarrow \mu_{2^n}$ , or a pseudorandom unitary, i.e.  $U_k \leftarrow \mu_{2^n}^k$ .
- Kretschmer [3] uses  $\mathcal{U}$  (quantum oracle) and  $\mathcal{C}$  (a classical oracle) which is independent of  $\mathcal{U}$ . The quantum oracle  $\mathcal{U}$  is defined as the set  $\{\mathcal{U}_n\}_{n \in \mathbb{N}}$  where for each  $n$ ,  $\mathcal{U}_n$  denotes a direct sum  $2^n$  independent Haar random unitaries, acting on  $n$  qubits, i.e.  $\mathcal{U}_n \leftarrow \mu_{2^n}^{\otimes n}$ .

**Exercise 3** (1 point; BQP=QMA yet PRUs exist). State the construction for the PRU ensemble used by Kretschmer.

Def<sup>1</sup>: PRU ensemble: For a given length  $n$ ,  
the PRU ensemble is uniform  
over the  $2^n$  different  $n$ -qubit  
unitaries in  $\mathcal{U}_n$ .

Notation: Denote by  $\{U_k\}_{k \in [N]}$  the PRU ensemble  
(for a fixed  $n$ )

So, basically, for a fixed  $n$ ,  $\mathcal{U}_n = (U_1 \oplus U_2 \dots \oplus U_{2^n})$   
and the ensemble is given by  
 $\{U_k\}_{k \in \{1, \dots, 2^n\}}$ .

#### Question 4

##### 5 QMA=BQP and yet PRUs exist

Question 4 (3 points). The answers to the following, should be enough for you to prove that the relative to  $\mathcal{U}$  (as defined above Exercise 3), PRUs exist.

- Fix the system size (on which the unitaries act) to be  $n$  qubits. Denote the PRU ensemble you defined in Exercise 3 as  $\tilde{\mathcal{U}} := \{\tilde{U}_k\}_{k \in \{0,1\}^n}$ . To establish that  $\tilde{\mathcal{U}}$  is a PRU, does it suffice to show that for all efficient quantum oracle-algorithms  $\mathcal{A}$ ,

$$\text{adv}(\mathcal{A}) := \Pr_{k \in \{0,1\}^n} [1 \leftarrow \mathcal{A}^{\tilde{U}_k}] - \Pr_{U \leftarrow \mu_{2^n}} [1 \leftarrow \mathcal{A}^U] \leq \text{negl}(n)? \quad [*]$$

If so, justify your answer (Hint: Do you need an  $\mathcal{U}$  to efficiently generate  $\tilde{\mathcal{U}}$ ? If so, should that appear somewhere in your definition of a secure PRU, relative to  $\mathcal{U}$ ?).

If not, how will you modify adv? (Hint: Note that  $\mathcal{C}$  is uncorrelated to  $\mathcal{U}$ )

(NB. You can neglect non-uniformity considerations i.e. it suffices, in the definition of PRUs to be secure against uniform adversaries—no need to consider advice, for the purposes of this exam).

- Suppose  $\mathcal{A}^{O,U}$  is an oracle algorithm that makes queries to  $U = (U_1, \dots, U_N) \in \mathbb{U}(D)^N$ . Prove that

$$\mathbb{E}_{U \leftarrow \mu_D^N} \left[ \Pr_{k \in [N]} [1 \leftarrow \mathcal{A}^{U_k, U}] \right] = \Pr_{k \in [N]} [1 \leftarrow \mathcal{B}^{e_k}] \quad (3)$$

where  $[N] = \{1, \dots, N\}$ ,  $e_k = (0, 0, \dots, 0, 1, 0, \dots, 0)$  with 1 at the  $k$ th position, and  $\mathcal{B}$  is defined as follows:

- $\mathcal{B}$  samples  $(V_0, V_1, \dots, V_N) \leftarrow \mu_D^{N+1}$  (which are unitaries in  $\mathbb{U}(D)^{N+1}$ ).
- $\mathcal{B}$  runs  $\mathcal{A}$ , replacing queries to  $O$  by queries to  $V_0$  and queries to  $U_k \in U$  by  $V_0$  if  $x_k = 1$ , and by  $V_k$  if  $x_k = 0$ .

Prove also that

$$\mathbb{E}_{U \leftarrow \mu_D^N} \left[ \Pr_{O \leftarrow \mu_D} [1 \leftarrow \mathcal{A}^{O, U}] \right] = \Pr [1 \leftarrow \mathcal{B}^{0^N}] \quad (4)$$

(NB. Using a bound on unstructured search, one can now argue that the difference between Eq. (3) and (4) must be at most  $cT^2/N$ , where  $T$  is the number of queries made by  $\mathcal{A}$  and  $c$  is a universal constant.)

#### Q4.1

[This question expects  $\tilde{\mathcal{U}}$  was defined as in Exercise 3.]

No, to establish that  $\tilde{\mathcal{U}}$  is a PRU,

one must, at the very least, show that [\*] holds  
even when access to  $\mathcal{U}$  is given (take  $n$  to be fixed for the moment).

More concretely, one must show, at the very least that  
the difference between the LHS of (3) and LHS of (4) is  
negligible.

"Very least" because one could also consider classical advice  
but we didn't cover this in class.

#### Q4.2

Here's the crux of the argument:

(I am taking  $N = 2^n$  but this doesn't change anything)

$\mathcal{A}^{U_k, U}$  basically sees  $2^n + 1$  oracles  
 $U_k, U_1, \dots, U_k, \dots, U_{2^n}$   
where the first oracle matches one of the remaining  $2^n$  oracles  
(in fact the  $k$ th of the remaining  $2^n$  oracles).

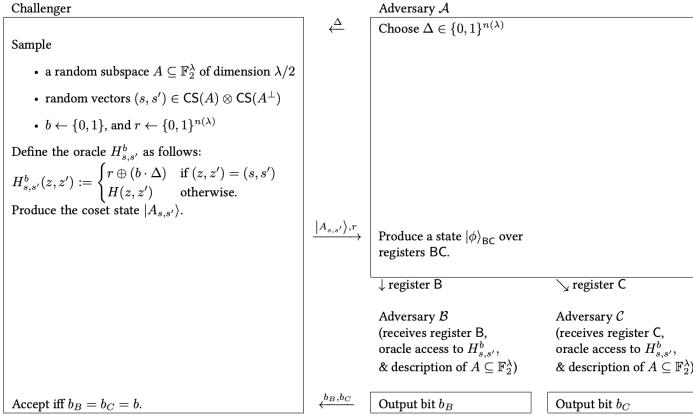

Now  $\mathcal{B}^{e_k}$  also runs  $\mathcal{A}$  with  $2^n + 1$  oracles,  
 $V_0, V_1, \dots, V_{k-1}, V_0, V_{k+1}, \dots, V_{2^n}$   
where the first oracle matches one of the remaining  $2^n$  oracles  
(in fact the  $k$ th of the remaining  $2^n$  oracles, as above).

And the distribution over  $(U_1, \dots, U_{2^n})$  is identical to that over  $(V_0, \dots, V_{k-1}, V_0, V_{k+1}, \dots, V_{2^n})$

because they are both sampled from  $\mu_D^N$ .

## Question 1

Reminder: Let us recall Hybrid 2 in the security proof of the uncloneable encryption scheme introduced by [1].

where

- $H$  is a random oracle  $H : \mathbb{F}_2^\lambda \times \mathbb{F}_2^\lambda \rightarrow \{0, 1\}^{n(\lambda)}$ ,
- $\mathcal{A}, \mathcal{B}, \mathcal{C}$  all get access to  $P_{A+s}$  and  $P_{A^\perp+s'}$  after the first message is sent by the challenger, and

- $\text{CS}(A)$  is the set of canonical representatives for  $A$ , i.e.  $\text{CS}(A) = \{\text{Can}_A(s) : s \in \mathbb{F}_2^n\}$ .
- $\text{Can}_A(s)$  is the (lexicographically) smallest vector in  $A + s := \{a + s : a \in A\}$ .
- $|A_{s,s'}⟩ := \frac{1}{\sqrt{|A|}} \sum_{a \in A} (-1)^{s' \cdot a} |a + s⟩$

For the proof, we will need to define projectors  $\Pi_0^B, \Pi_1^B, \Pi_0^C, \Pi_1^C$ . For a fixed  $A, r, \Delta, s, s'$  they are defined as follows:

- $\Pi_0^B$ : runs  $\mathcal{B}$  with oracle access to  $H_{s,s'}^0$  ( $B$  and  $A$  are the same), projects on outcome 0, and undoes the computation.
- $\Pi_1^B$ : runs  $\mathcal{B}$  with oracle access to  $H_{s,s'}^1$  ( $B$  and  $A$  are the same), projects on outcome 1, and undoes the computation.
- $\Pi_0^C$  and  $\Pi_1^C$  are defined similarly, with  $\mathcal{B}$ ,  $B$  replaced with  $\mathcal{C}$ ,  $C$ .

We will need some more notation.

- Denote by  $\{(|\phi_i⟩, \lambda_i)\}_i$  the (eigenvectors, eigenvalues) of  $(\Pi_0^B + \Pi_1^B)/2$ . Similarly, let  $\{(|\psi_j⟩, \mu_j)\}_j$  denote the corresponding quantities for  $(\Pi_0^C + \Pi_1^C)/2$ .
- NB:  $|\phi⟩_{BC} = \sum_{ij} \alpha_{ij} |\phi_i⟩_B \otimes |\psi_j⟩_C$  without loss of generality.

Finally, we will assume the following holds about the state  $|\phi⟩_{BC}$  produced by  $\mathcal{A}$ : for every polynomial  $p$ , we have

$$\sum_{\substack{i: |\lambda_i - 1/2| \leq 1/p \\ j: |\mu_j - 1/2| \leq 1/p}} |\alpha_{ij}|^2 \leq \text{negl}(n).$$

**Question 1** (3 points). Denote by  $p_2$  the probability that Hybrid 2 above outputs accept. We will show some of the main steps in establishing that  $p_2 \leq \frac{1}{2} + \text{negl}(n)$ .

1. Show that the state  $|\phi⟩_{BC}$  is negligibly close to

$$|\phi⟩_{BC} := \sum_{i: |\lambda_i - 1/2| \leq 1/p} \alpha_{ij} |\phi_i⟩_B \otimes |\psi_j⟩_C + \sum_{\substack{i: |\lambda_i - 1/2| > 1/p \\ j: |\mu_j - 1/2| \leq 1/p}} \alpha_{ij} |\phi_i⟩_B \otimes |\psi_j⟩_C.$$

2. Show that

$$\frac{1}{2} \left( |\langle (\Pi_0^B \otimes \Pi_0^C) |\phi⟩_{BC} |^2 + |\langle (\Pi_1^B \otimes \Pi_1^C) |\phi⟩_{BC} |^2 \right) \quad (1)$$

is negligibly close to the probability that  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  is accepted by the Challenger.

3. Show that the expression above (Eq 1) can be upper bounded by

$$\begin{aligned} \frac{1}{2} \cdot & \left( \underbrace{\langle \phi'_B | (\Pi_0^B \otimes I) |\phi'_B \rangle}_{\text{I}} + \langle \phi'_B | (\Pi_1^B \otimes I) |\phi'_B \rangle + \underbrace{\langle \phi'_C | (I \otimes \Pi_0^C) |\phi'_C \rangle}_{\text{II}} + \langle \phi'_C | (I \otimes \Pi_1^C) |\phi'_C \rangle \right) \\ & + \Re \left( \underbrace{\langle \phi'_C | (\Pi_0^B \otimes \Pi_0^C) |\phi'_C \rangle}_{\text{III}} + \underbrace{\langle \phi'_B | (\Pi_1^B \otimes \Pi_1^C) |\phi'_C \rangle}_{\text{IV}} \right). \end{aligned}$$

4. Establish that I (resp. II) is at most  $\left(\frac{1}{2} + \frac{1}{p}\right) \|\phi'_B\|^2$  (resp.  $\left(\frac{1}{2} + \frac{1}{p}\right) \|\phi'_C\|^2$ ).

5. Suppose it holds that for indices  $i, i'$  satisfying  $\lambda_i + \lambda_{i'} \neq 1$ , we have  $\langle \phi_i | \Pi_0^B | \phi_{i'} \rangle = 0$  (we proved this in class). Using this, show that both III and IV are zero.

6. Quick conceptual questions:

- (a) In your answers above, where did you (most directly) use properties of the coset state  $|A_{s,s'}\rangle$ ?  
(b) Assertion:  $\Pi_0^B + \Pi_1^B = \mathbb{I}$ . Either prove the assertion or justify why you don't expect the projectors to sum to identity.  
(NB. Combining these, you should be able to deduce that  $p_2 \leq \left(\frac{1}{2} + \frac{1}{p}\right)(|\phi'_B\rangle|^2 + |\phi'_C\rangle|^2) + \text{negl} \leq \frac{1}{2} + \frac{1}{p} + \text{negl}$  and since this is true for all polynomials  $p$ , we have proved  $p_2 \leq \frac{1}{2} + \text{negl}$ .)

Question 1.1, 1.2, 1.3, 1.4 and 1.5 are basically straight from the paper (see below).

### Question 1.6

- (a) The answer for me is step (2) because this is where we use the fact that  $|\phi\rangle_{BC}$  has the form we assumed it does and also corresponds to the success probability of  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$ .

(The coset states are basically used to prove that  $|\phi\rangle_{BC}$  has the form it does.)

Other answers may also be fine, as long as they are justified appropriately. Judge for yourselves.

- (b) We don't expect the projectors to sum to 1 because they don't correspond to different outcomes of the same measurement, i.e.

$\Pi_0^B$  uses oracle  $H_{s,s'}^0$ , while  $\Pi_1^B$  uses oracle  $\Pi_{s,s'}^1$ .  
(if they were using the same oracle, then one would expect them to sum to 1).

Let  $|\phi_{BC}\rangle$  be the state prepared by  $\mathcal{A}$ . Without loss of generality, we can assume the state is pure. We write the state under the basis  $\{|\phi_i\rangle\}_i$  and  $\{|\psi_j\rangle\}_j$ :

$$|\phi_{BC}\rangle = \sum_{i,j} \alpha_{i,j} |\phi_i\rangle_B \otimes |\psi_j\rangle_C.$$

**Lemma 4.12.** Taken the randomness of  $A, s, s'$  and  $H_{-s,s'}$ , for every polynomial  $p(\cdot)$ , there exists a negligible function  $\text{negl}$  such that with overwhelming probability the following weight is bounded:

$$\sum_{\substack{i: |\lambda_i - 1/2| > 1/p \\ j: |\mu_j - 1/2| > 1/p}} |\alpha_{i,j}|^2 \leq \text{negl}(n).$$

The proof for this lemma is given at the end of this section.

With the above lemma, we can claim that over the randomness of  $A, s, s'$  and  $H_{-s,s'}$ , for every polynomial  $p(\cdot)$ ,  $|\phi_{BC}\rangle$  is negligibly close to the following state  $|\phi'_{BC}\rangle$ :

$$\sum_{i: |\lambda_i - 1/2| \leq 1/p} \alpha_{i,j} |\phi_i\rangle_B \otimes |\psi_j\rangle_C + \sum_{\substack{i: |\lambda_i - 1/2| > 1/p \\ j: |\mu_j - 1/2| \leq 1/p}} \alpha_{i,j} |\phi_i\rangle_B \otimes |\psi_j\rangle_C.$$

For convenience, we name the left part as  $|\phi'_B\rangle$  (indicating  $\mathcal{B}$  can not win) and the right part as  $|\phi'_C\rangle$  (indicating  $\mathcal{C}$  can not win). Thus, for every polynomial  $p(\cdot)$ , there exists a negligible function

$\text{negl}(\cdot)$ ,  $||\phi_{BC}\rangle - (|\phi'_B\rangle + |\phi'_C\rangle)||_1$  is at most  $\text{negl}(\cdot)$  (in expectation, taken the randomness of  $A, s, s', r$  and  $H_{-s,s'}$ ).

The probability that  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  wins is at most:

$$(|(\Pi_0^B \otimes \Pi_0^C)|\phi'_{BC}\rangle|^2 + |(\Pi_1^B \otimes \Pi_1^C)|\phi'_{BC}\rangle|^2)/2.$$

$\Pi_0^B \otimes \Pi_0^C$  is the case that they both get access to  $H_0$  and  $\Pi_1^B \otimes \Pi_1^C$  for  $H_1$ .

The probability is at most

$$\begin{aligned} & (|(\Pi_0^B \otimes \Pi_0^C)|\phi'_B\rangle + |\phi'_C\rangle)^2 + |(\Pi_1^B \otimes \Pi_1^C)(|\phi'_B\rangle + |\phi'_C\rangle)|^2)/2 \\ &= \frac{1}{2} \cdot ((\phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_B\rangle + \langle \phi'_B|(\Pi_0^B \otimes \Pi_0^C)\phi'_B\rangle + \langle \phi'_C|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle + \langle \phi'_C|(\Pi_1^B \otimes \Pi_1^C)|\phi'_C\rangle) \\ &+ \text{Re}((\phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle + \langle \phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle)) \\ &\leq \frac{1}{2} \cdot ((\phi'_B|(\Pi_0^B \otimes I)|\phi'_B\rangle + \langle \phi'_B|(\Pi_0^B \otimes I)|\phi'_B\rangle + \langle \phi'_C|(I \otimes \Pi_0^C)|\phi'_C\rangle + \langle \phi'_C|(I \otimes \Pi_0^C)|\phi'_C\rangle) \\ &+ \text{Re}((\phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle + \langle \phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle)). \end{aligned}$$

We bound each term separately.

- $\frac{1}{2} (|\langle \phi'_B|(\Pi_0^B \otimes I)|\phi'_B\rangle + \langle \phi'_B|(\Pi_0^B \otimes I)|\phi'_B\rangle)$ . It is equal to  $\langle \phi'_B|(\Pi_0^B + \Pi_1^B)/2 \otimes I|\phi'_B\rangle$ ; by the definition of  $|\phi'_B\rangle$ , it will be at most  $(\frac{1}{2} + \frac{1}{p})||\phi'_B\rangle|^2$ .
- $\frac{1}{2} (|\langle \phi'_C|(I \otimes \Pi_0^C)|\phi'_C\rangle + \langle \phi'_C|(I \otimes \Pi_1^C)|\phi'_C\rangle)$ . Similar to the above case, it is at most  $(\frac{1}{2} + \frac{1}{p})||\phi'_C\rangle|^2$ .
- $\text{Re}((\phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle))$ . By Corollary 2.4, the inner product will be 0:

$$\langle \phi'_B|(\Pi_0^B \otimes \Pi_0^C)|\phi'_C\rangle = \sum_{i: |\lambda_i - 1/2| \leq 1/p} \sum_{\substack{i': |\lambda_{i'} - 1/2| > 1/p \\ j': |\mu_{i'} - 1/2| \leq 1/p}} \alpha_{i,j}^\dagger \alpha_{i',j'} \langle \phi_i|\Pi_0^B|\phi_{i'}\rangle \langle \psi_j|\Pi_0^C|\psi_{j'}\rangle;$$

since every possible  $i, i'$  satisfy  $\lambda_i + \lambda_{i'} \neq 1$ , we have  $\langle \phi_i|\Pi_0^B|\phi_{i'}\rangle = 0$ .

- $\text{Re}((\phi'_B|(\Pi_1^B \otimes \Pi_1^C)|\phi'_C\rangle))$ . By Corollary 2.4, the inner product will be 0 as well.

Therefore, the total probability will be at most  $(\frac{1}{2} + \frac{1}{p})(||\phi'_B\rangle|^2 + ||\phi'_C\rangle|^2) + \text{negl}(n) \leq \frac{1}{2} + \frac{1}{p} + \text{negl}(n)$

$\text{negl}(n)$ .

Since the above statement holds for every polynomial  $p(\cdot)$ , it finishes the proof for [Theorem 4.8](#).  $\square$

**Corollary 2.4.** For any two projectors  $\Pi_0, \Pi_1$ , let  $|\phi_0\rangle$  and  $|\phi_1\rangle$  be two eigenvectors of  $w\Pi_0 + (1-w)\Pi_1$  with eigenvalues  $\lambda_0, \lambda_1$ . If  $\lambda_0 + \lambda_1 \neq 1$  and  $\lambda_0 \neq \lambda_1$ , then

$$\langle\phi_0|\Pi_0|\phi_1\rangle = \langle\phi_0|\Pi_1|\phi_1\rangle = 0.$$

*Proof.* If  $\lambda_0 + \lambda_1 \neq 1$ , by [Lemma 2.3](#),  $|\phi_0\rangle$  and  $|\phi_1\rangle$  cannot be in the same Jordan block. Because  $|\phi_0\rangle$  still belongs to the corresponding subspace  $S_0$  of its Jordan block after the action of  $\Pi_0$ ,  $\Pi_0|\phi_0\rangle$  is orthogonal to  $|\phi_1\rangle$ . Similarly,  $\Pi_1|\phi_0\rangle$  is orthogonal to  $|\phi_1\rangle$ .  $\square$

## Question 7

Reminder:

- An XZ Local Hamiltonian acting on  $n$  qubits is of the form  $H = \sum_{\ell \in [m]} \gamma_\ell H_\ell$  where  $H_\ell$  consists of tensor products of  $\sigma_x$  and  $\sigma_z$  (and  $\mathbb{I}$ ) matrices, acting non-trivially (i.e. non  $\mathbb{I}$ ) on at most  $k$  qubits, i.e. for each  $\ell$ ,  $H_\ell = \otimes_{j \in n} \sigma_{W_{j,\ell}} \in \{\sigma_x, \sigma_z, \sigma_I\}^{\otimes n}$  with  $|\{j | j \in [n] \wedge \sigma_{W_{j,\ell}} \neq \sigma_I\}| \leq k$ .
- The Hamiltonian Test  $G(H)$  for such Hamiltonians, as constructed by [\[2\]](#), is as shown in Figure 2 ( $t$  below is taken to be something like  $n \log n$ ).
- In class, we proved the following (as Lemma 7). Let  $\omega_h(H) := 1 - p\left(\frac{1}{2m} \sum_{\ell \in [m]} |\gamma_\ell| - \frac{1}{2}\lambda_0(H)\right)$  where  $\lambda_0(H)$  denotes the smallest eigenvalue of  $H$ . If the provers use the honest strategy in the Pauli-Braiding test, then the maximum acceptance probability in  $G(H)$  is  $\omega_h(H)$ . We now write down some of the main steps that go into this proof and you will be asked to fill in some of the gaps in the argument.

**Question 7** (2 points, Verification). Prove the following assertions.

- Assertion: The acceptance probability in  $G(H)$  depends uniquely on the strategy of the first prover in the energy test (in particular, it does not depend on the strategy of the second prover in the energy test).

- Assertion: For a fixed  $H_\ell$ , the verifier rejects with probability

$$\frac{|\gamma_\ell| + \gamma_\ell \mathbb{E}[\Pi_{i \in [n]} d_i]}{2}. \quad (5)$$

Denote by  $\tau$  the reduced state held by the second prover on qubits  $\mathcal{T} := (\mathcal{T}_1, \dots, \mathcal{T}_n)$  of his EPR halves (after ‘teleportation’).

- Assertion: Given the answers  $(a, b)$  of the first prover, the following behaviours of the second prover are equivalent:

- Measure  $\tau$  using  $H_\ell$  and obtain outcome  $\Pi_{i \in \mathcal{T}} c_i$ .
- Measure  $\rho = Z^b X^a \tau X^a Z^b$  using  $H_\ell$  and obtain outcome  $\Pi_{i \in \mathcal{T}} d_i$ .

*Hint: Measuring a qubit  $|\phi\rangle$  in the  $Z$ -basis w/outcome  $f \in \{\pm 1\}$  is equivalent to getting outcome  $(-1)^g f$  when measuring  $Z^h X^g |\phi\rangle$  in the  $Z$ -basis. Similarly, measuring  $|\phi\rangle$  in the  $X$ -basis w/outcome  $f \in \{\pm 1\}$  is equivalent to getting outcome  $(-1)^h f$  when measuring  $Z^h X^g |\phi\rangle$  in the  $X$ -basis. (Equivalence as in the output distribution is identical).*

- Assertion: The rejection probability in Eq (5), averaged over  $\ell$ , is

$$\frac{1}{2m} \sum_{\ell \in [m]} |\gamma_\ell| + \frac{1}{2} \text{tr}(\rho H).$$

The acceptance probability in  $G(H)$  is at most

$$1 - p\left(\frac{1}{2m} \sum_{\ell \in [m]} |\gamma_\ell| - \frac{1}{2}\lambda_0(H)\right) = \omega_h(H).$$

(a) Pauli-Braiding Test: (We don't need the details here, except that the view of Prover 2 is exactly the same as that in the Energy Test).

(b) Energy Test

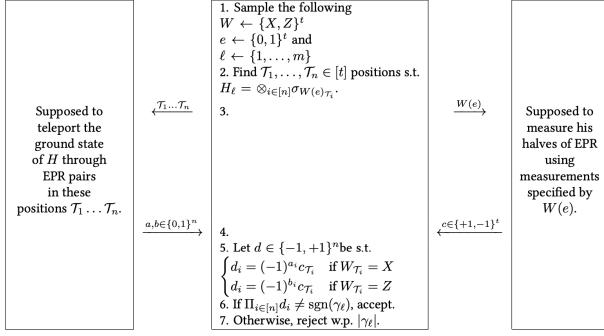

Figure 2: The verifier performs the Pauli-Braiding Test with probability  $1 - p$  and the Energy Test with probability  $p$ . The provers are assumed to share  $t$  EPR pairs.

### Question 7.1

NB1.

The view of the second prover is exactly the same whether the Pauli-braiding test is run or the Energy test is run.

NB2:

Both provers are assumed to be honest in the Pauli-braiding test.

Conclusion.

The second prover must behave identically to how it behaves in the energy test.

And therefore,

the acceptance probability in  $G(H)$  depends uniquely on the strategy of the first prover in the energy test.

(these are hints, the actual answers must explain these in detail)

### Question 7.2

One has to work out the probability that the signs match and after some algebra, one obtains the right expression.

### Question 7.3

This essentially follows from the definitions of  $c_i$  of  $d_i$  and the property about measuring  $X^g Z^h |\phi\rangle$  in  $Z$ -basis and getting outcome  $(-1)^g f$ .

See that it is explained clearly.

### Question 7.4

from the previous step you get  $\text{tr}(H_l \rho) = \mathbb{E}[\prod_{i \in [n]} d_i]$  and then the weighted average gives you  $\text{tr}(H \rho)$ .
